Redirect

The domain name is set to a A record. This A record redirects us to the URL set on the web interface.

There are currently two types of redirects:

- **HTTP**: In this case, the visitor to the page will be redirected to the specified address and the URL will be overwritten in the browser. So the address of the new web page will appear in the browser bar. (This is what we recommend because search engines like this kind of redirection)
- **FRAME**: In that case, the page you are redirected will be loaded into an iFrame, leaving the original page title in the browser's title bar. (We do not recommend this because iFrame is not popular with search engines and it is not sure that the page you are loading will work properly.)
